

Basic idea: if a small change in an MPS is to be computed (e.g. during variational optimization or time-evolution with a small time step), this change lives in the 'tangent space' of the manifold defined by the MPS. Thus, construct a projector onto the tangent space, and implement gauge fixing conditions to remove redundancy due to gauge degrees of freedom. [Haegeman2011]

FIG. 1. A sketch of the manifold $\mathcal{M} = \mathcal{M}_{\text{uMPS}}$ (wire frame) embedded in state space. The tangent plane $T_A \mathcal{M}$ to \mathcal{M} (rotated gray square) in a uMPS $|\psi(A)\rangle$ (black dot) is spanned by generally nonorthogonal coordinate axes $|\partial_1 \psi(A)\rangle$ and $|\partial_2 \psi(A)\rangle$ (dotted lines). The direction $i\hat{H}|\psi(A)\rangle$ of time evolution (arrow with solid head) is best approximated by its orthogonal projection into the tangent plane (arrow with open head). The optimal path $|\psi(A(t))\rangle$ (gray curve) follows the vector field generated by these orthogonally projected vectors throughout \mathcal{M} .

This very fundamental and general idea has been elaborated in a series of publications.

This lecture follows [Haegeman2016], formulated for finite MPS with open boundary conditions.

1. MPS and canonical forms (reminder)

Consider N-site MPS with open boundary conditions:

$$|\psi[M]\rangle = |\bar{\sigma}_N\rangle M_{[1]}^{\sigma_1} M_{[2]}^{\sigma_2} \dots M_{[N]}^{\sigma_N}$$

where $M_{[l]}^{\sigma_l}$ is matrix with elements $M_{[\alpha][\beta]}^{\sigma_l}$, of dimension $D_{l-1} \times D_l$, with $D_0 = D_N = 1$

shorthand: $M \equiv (M_{[1]}, \dots, M_{[N]}) \in \mathbb{M}$ space of tensors with specified dimensions

Gauge freedom: $|\psi[M]\rangle$ is unchanged under 'gauge transformation' on bond indices:

$$M_1 \dots M_N \mapsto \tilde{M}_1 \dots \tilde{M}_N = M_1 G_1 G_1^{-1} G_2^{-1} G_2 \dots G_{N-1} G_{N-1}^{-1} M_N \quad (2)$$

$$M_{[l]}^{\sigma_l} \mapsto \tilde{M}_{[l]}^{\sigma_l} \equiv G_{[l-1]}^{-1} M_{[l]}^{\sigma_l} G_{[l]} \quad , \quad G_{[1]} = G_{[N]} = 1 \quad (3)$$

with $G_{[l]} \in GL(D_l, \mathbb{C})$ group of general complex linear transformation in D_l dimensions

Note: H and M are vector spaces, but M_{MPS} is not, since sum of two MPS with same bond dimensions in general is an MPS with larger bond dimensions. M_{MPS} is a differential manifold, since it depends smoothly on the tensors in M .

Gauge freedom can be exploited to bring MPS into left-, right-, bond- or site-canonical form:

Left-canonical: $|\psi[M]\rangle = \begin{array}{c} A \quad A \quad A \quad A \quad A \\ \downarrow \downarrow \downarrow \downarrow \downarrow \\ \text{---} \end{array}$ with $\begin{array}{c} \leftarrow \\ \downarrow \\ \leftarrow \end{array} = \mathbb{1}$ (4)

Gauge can be fixed uniquely by requiring $A_\sigma^\dagger A_\sigma = \mathbb{1}$ and $A_\sigma^\dagger A_\sigma = \text{diagonal} \forall A_{[\sigma]}$

Right-canonical: $|\psi[M]\rangle = \begin{array}{c} B \quad B \quad B \quad B \quad B \\ \leftarrow \leftarrow \leftarrow \leftarrow \leftarrow \\ \text{---} \end{array}$ with $\begin{array}{c} \leftarrow \\ \downarrow \\ \leftarrow \end{array} = \mathbb{1}$ (5)

Gauge can be fixed uniquely by requiring $B_\sigma^\dagger B_\sigma = \mathbb{1}$ and $B_\sigma^\dagger B_\sigma = \text{diagonal} \forall B_{[\sigma]}$

Site-canonical: $|\psi[M]\rangle = \begin{array}{c} A \quad A \quad C \quad B \quad B \\ \downarrow \downarrow \downarrow \downarrow \downarrow \\ \text{---} \end{array} = |\beta\rangle_{l+1}^R |\sigma_l\rangle |\alpha\rangle_{l-1}^L C_{[\sigma]}^{\alpha\beta}$ (6)

Here $|\alpha\rangle_{l-1}^L$ and $|\beta\rangle_{l+1}^R$ are orthonormal basis for subspaces representing left- and right parts of chain.

Hamiltonian matrix elements:

$\sum_{\alpha'} \langle \alpha' | \langle \sigma'_l | \langle \beta' | \hat{H} | \beta \rangle_{l+1} | \sigma_l \rangle | \alpha \rangle_{l-1} = \begin{array}{c} \alpha \quad \sigma_l \quad \beta \\ \downarrow \downarrow \downarrow \\ \text{---} \\ \uparrow \uparrow \uparrow \\ \alpha' \quad \sigma'_l \quad \beta' \end{array} = \begin{array}{c} \leftarrow \\ \downarrow \\ \leftarrow \end{array} H_{[\sigma]} \begin{array}{c} \leftarrow \\ \downarrow \\ \leftarrow \end{array}$ (7)

Bond-canonical: $|\psi[M]\rangle = \begin{array}{c} A \quad A \quad A \quad B \quad B \\ \downarrow \downarrow \downarrow \downarrow \downarrow \\ \text{---} \end{array} = |\beta\rangle_{l+1}^R |\alpha\rangle_l^L \Lambda_{[\sigma]}^{\alpha\beta}$

related to site-canonical form by

$C_{[\sigma]} = A_{[\sigma]} \Lambda_{[\sigma]} = \Lambda_{[\sigma-1]} B_{[\sigma]}$

Hamiltonian matrix elements:

$\sum_{\alpha'} \langle \alpha' | \langle \beta' | \hat{H} | \beta \rangle_{l+1} | \alpha \rangle_l = \begin{array}{c} \alpha \quad \beta \\ \downarrow \downarrow \\ \text{---} \\ \uparrow \uparrow \\ \alpha' \quad \beta' \end{array} = \begin{array}{c} A_{[\sigma]} \\ \downarrow \\ \leftarrow \end{array} K_{[\sigma]} \begin{array}{c} \leftarrow \\ \downarrow \\ \leftarrow \end{array} A_{[\sigma]}^\dagger$ (12)

Time-dependent Schrödinger equation:
$$-i \frac{d}{dt} |\psi(t)\rangle = \hat{H} |\psi(t)\rangle \quad (1)$$

General solution is (t-dependent) vector in full many-body Hilbert space, \mathbb{H} , of dimension d^N .

Goal: find (approximate) solution as (t-dependent) point in space of MPS with tensors of specified dimensions:

$$|\psi[M(t)]\rangle = \begin{array}{c} M_{(1)}(t) \quad M_{(2)}(t) \quad M_{(N)}(t) \\ \hline \end{array} \in \mathcal{M}_{MPS} \quad (2)$$

Then
$$\frac{d}{dt} |\psi[M(t)]\rangle = \sum_{\ell=1}^N \begin{array}{c} M_{(1)} \quad M_{(\ell-1)} \quad \dot{M}_{(\ell)} \quad M_{(\ell+1)} \quad M_{(N)} \\ \hline \end{array} \equiv |\Phi[\dot{M}]\rangle_{M(t)} \quad (3)$$

Here we have introduced the general notation

$$|\Phi[T]\rangle_M = \sum_{\ell=1}^N \begin{array}{c} M_{(1)} \quad M_{(\ell-1)} \quad T_{(\ell)} \quad M_{(\ell+1)} \quad M_{(N)} \\ \hline \end{array} \equiv |\partial_{\mathbf{j}} \psi[M]\rangle T^{\mathbf{j}} \quad (4)$$

shorthand: $T \equiv (T_{(1)}, \dots, T_{(N)}) \in \mathbb{M}$ with composite index $\mathbf{j} = (\ell, \alpha, \sigma, \beta)$

For a given set of tensors $M \in \mathbb{M}$, specifying a given MPS $|\psi[M]\rangle \in \mathcal{M}_{MPS}$, the space of all states $|\Phi[T]\rangle_M$ with $T \in \mathbb{M}$, is a vector space (since $|\Phi[T]\rangle$ is linear in T). It is called the 'tangent space', $\mathbb{T}_{|\psi[M]\rangle}$, associated with the 'base point' $|\psi[M]\rangle$ in the manifold \mathcal{M}_{MPS} .

Remark: the gauge freedom available for describing $|\psi[M]\rangle$ implies a related gauge freedom available for constructing its tangent space. We obtain a unique construction via the following criteria:

- (i) We pick a representative M along each ~~fiber~~ ^{orbit} (fix gauge for $|\psi[M]\rangle$), e.g. by picking one of the canonical forms.
- (ii) Changes of M pointing 'along an orbit' amount to gauge transformations and do not change $|\psi[M]\rangle$. To construct tangent space $\mathbb{T}_{|\psi[M]\rangle}$, we consider only T 's describing changes of M

(ii) Changes of $|\psi\rangle$ pointing along an orbit amount to gauge transformations and do not change $|\psi[M]\rangle$. To construct tangent space $\Pi_{|\psi[M]\rangle}$, we consider only T 's describing changes of M orthogonal to such directions.

(iii) Since time evolution is unitary (norm-preserving), $\langle \psi(t) | \psi(t) \rangle = 1$, we consider only T 's describing changes of M producing tangent vectors orthogonal to $|\psi[M]\rangle$ itself.

We denote the vector space of T 's satisfying these conditions by Π_M^\perp .

Then each $T \in \Pi_M^\perp$ uniquely specifies a corresponding tangent vector $|\Phi[T]\rangle_M$ in $\Pi_{|\psi[M]\rangle}^\perp$, the subset of tangent space orthogonal to $|\psi[M]\rangle$ (w.r.t. scalar product in Hilbert space \mathbb{H}):

$$\langle \Phi[T]_M | \Psi[M] \rangle = 0 \quad \forall T \in \Pi_M^\perp \quad (5)$$

According to (3) and (iii), left-hand side of Schrödinger equation, $-i \frac{d}{dt} |\psi(t)\rangle$, is in $\Pi_{|\psi[M]\rangle}^\perp$.

However, the right side, $\hat{H} |\psi(t)\rangle$, is not. In fact, action of \hat{H} in general produces MPS with

larger bond dimensions. Our decision to solve time evolution within \mathcal{M}_{MPS} of specified dimension

thus inevitably involves an approximation. The best we can then do is to project $\hat{H} |\psi(t)\rangle$ into

orthogonal tangent space $\Pi_{|\psi[M(t)]\rangle}^\perp$, using a projector $\hat{P}_{\Pi_{|\psi[M(t)]\rangle}^\perp}$, and write Schrödinger eq. as

$$-i \frac{d}{dt} |\psi[M(t)]\rangle = \hat{P}_{\Pi_{|\psi[M(t)]\rangle}^\perp} \hat{H} |\psi[M(t)]\rangle \quad (6)$$

To implement this idea explicitly, we need explicit construction of the projector \hat{P} .

'time-dependent variational principle' (TDVP)

3. Tangent space projector

TS.3

General form of tangent vector:
$$\sum_{\ell=1}^N M_{[\ell]} \quad \begin{array}{c} M_{[\ell-1]} \quad \tilde{T}_{[\ell]} \quad M_{[\ell+1]} \\ \hline M_{[\ell]} \end{array} \quad (1)$$

Gauge freedom can be used to bring ℓ -th summand into site-canonical form w.r.t. to site ℓ :

$$|\Phi[T]\rangle_M = \sum_{\ell=1}^N \begin{array}{c} A_{[\ell]} \quad A_{[\ell-1]} \quad T_{[\ell]} \quad B_{[\ell+1]} \quad B_{[\ell]} \\ \hline \end{array} \quad (2)$$

There is still gauge freedom left: $|\Phi[T]\rangle_M$ does not change under the replacement

$$T_{[\ell]} \mapsto \tilde{T}_{[\ell]} = T_{[\ell]} + Y_{[\ell-1]} B_{[\ell]} - A_{[\ell]} Y_{[\ell]} \quad , \quad Y_{[0]} = Y_{[N]} = 0. \quad (3)$$

$A^+ \tilde{T} = 0$ $A^+(T + YB - AY) = 0$
with $Y_{[\ell]}$ an arbitrary matrix of dimensions $D_{\ell} \times D_{\ell}$

Check: extra terms yield
$$\left(\sum_{\ell=2}^N \begin{array}{c} A_{[\ell]} \quad A_{[\ell-1]} \quad Y_{[\ell-1]} \quad B_{[\ell]} \quad B_{[\ell+1]} \quad B_{[\ell]} \\ \hline \end{array} - \sum_{\ell=1}^{N-1} \begin{array}{c} A_{[\ell]} \quad A_{[\ell-1]} \quad A_{[\ell]} \quad Y_{[\ell]} \quad B_{[\ell+1]} \quad B_{[\ell]} \\ \hline \end{array} \right) \quad (4)$$

This freedom can be exploited to impose the following 'left gauge fixing condition' (LGFC) on $T_{[\ell]}$:

$$A_{[\ell]}^+ T_{[\ell]} = 0 \quad \forall \ell = 1, \dots, N-1 \quad \begin{array}{c} T \\ \hline A^+ \end{array} = 0 \quad (5)$$

[If T does not satisfy LGFC, replace it by \tilde{T} , with Y chosen such that \tilde{T} does satisfy LGFC.]

The LGFC has two convenient properties. First, it ensures orthogonality of tangent vector to its base point vector:

$$\langle \psi[M] | \Phi[T] \rangle_M = \sum_{\ell=1}^N \begin{array}{c} A \quad A \quad T \quad B \quad B \\ \hline A^+ \quad A^+ \quad A^+ \quad A^+ \end{array} = 0 \quad (6)$$

as required by property (iii) of Sec. TS.2. Second, it enables construction of an orthonormal basis for the orthogonal tangent space $\Pi_{|\psi[M]\rangle}^{\perp}$. To this end, we adopt a more convenient parameterization of $T_{[\ell]}$.

$$D^d \begin{pmatrix} \cdot \\ \cdot \\ \cdot \end{pmatrix} = \overset{D}{\text{hd}} \begin{pmatrix} D \\ D \\ D \end{pmatrix} \begin{pmatrix} D \\ D \\ D \end{pmatrix} \begin{pmatrix} D \\ D \\ D \end{pmatrix} \quad \begin{array}{c} U=A \quad S \quad v^+ \\ \hline d \quad D \quad D \quad D \end{array}$$

Parameterization of $T_{[\ell]}$:

Recall that each $A_{[\ell]}^{\sigma}$ was obtained by 'thin' SVD of some $M_{[\ell]}^{\sigma}$. Let us consider corresponding 'fat' SVD:

$$M_{[\ell]}^{\sigma} = U_{[\ell]}^{\sigma} \Sigma_{[\ell]}^{\sigma} V_{[\ell]}^{\sigma}$$

Recall that each $A_{[el]}^\sigma$ was obtained by 'thin' SVD of some $M_{[el]}^\sigma$. Let us consider corresponding 'fat' SVD:

$$D' \begin{array}{c} M^\sigma \\ \hline d \end{array} D \stackrel{\text{fat SVD}}{=} D' \begin{array}{c} U^\sigma \\ \hline d \\ \hline D'd \\ \hline D'd \end{array} S \begin{array}{c} V^\dagger \\ \hline D \end{array} \quad (7)$$

$$D'd \begin{pmatrix} D \\ \hline \end{pmatrix} = D'd \begin{pmatrix} A^\sigma \\ \hline A'^\sigma \\ \hline \end{pmatrix} \begin{pmatrix} S & 0 \\ \hline 0 & 0 \end{pmatrix} \begin{pmatrix} D \\ \hline D'd-D \\ \hline \end{pmatrix} \quad (8)$$

$\underbrace{D'd-D}_{D''}$

A^σ is built from the first D columns of the $D'd \times D'd$ unitary matrix U^σ : $D' \begin{array}{c} A^\sigma \\ \hline d \end{array} U$

Let A'^σ be similarly built from its remaining $D'' = D'd - D$ columns: $D' \begin{array}{c} A'^\sigma \\ \hline d \end{array} D''$

Since U is unitary, the columns of A and A' form orthonormal bases of mutually orthogonal subspaces:

$$U_\sigma^\dagger U^\sigma = \mathbf{1}_{dD'd \times dD'd} \Rightarrow A_\sigma^\dagger A^\sigma = \mathbf{1}_{D \times D}, \quad A_\sigma^\dagger A'^\sigma = \mathbf{1}_{D'' \times D''}, \quad A_\sigma^\dagger A'^\sigma = 0 \quad (9)$$

$$\left(\begin{array}{c} A^\dagger \\ \hline A'^\dagger \end{array} \right) \left(\begin{array}{c} A \\ \hline A' \end{array} \right) = \mathbf{1} \quad \begin{array}{c} \left(\begin{array}{c} A \\ \hline A' \end{array} \right) \left(\begin{array}{c} A^\dagger \\ \hline A'^\dagger \end{array} \right) = \mathbf{1} \\ \left(\begin{array}{c} A \\ \hline A' \end{array} \right) \left(\begin{array}{c} A^\dagger \\ \hline A'^\dagger \end{array} \right) = 0 \end{array} \quad (10)$$

Exploiting orthogonality of A and A' , we can parametrize T in following factorized form

$$T_{[el]}^\sigma = A'^{\sigma 2} X_{[el]}, \quad D' \begin{array}{c} T^\sigma \\ \hline d \end{array} D = D' \begin{array}{c} A'^\sigma \\ \hline d \\ \hline D'd-D \\ \hline D \end{array} X \quad (11)$$

where $X_{[el]}$ is an arbitrary $(D'd - D) \times D$ matrix, and (9, far right) ensures that LGFC (5) holds.

After left-gauge-fixing, tangent vectors have the following general form, parametrized by X :

$$|\Phi[X]\rangle_M^{(i), (ii)} = \sum_{\ell=1}^N \begin{array}{c} A \rightarrow \rightarrow \rightarrow A_{\ell-1} \rightarrow A'_{\ell\alpha} X_{\ell\beta}^\alpha \rightarrow B_{\ell+1} \leftarrow \leftarrow \leftarrow B \\ \hline \alpha \quad \beta \end{array} \equiv \sum_{\ell=1}^N X_{[el]}^{\alpha\beta} |\Phi_{\ell, \alpha\beta}\rangle_M \quad (12)$$

Here the set of states $|\Phi_{\ell, \alpha\beta}\rangle_M \equiv \begin{array}{c} A_{\ell\alpha} \rightarrow \rightarrow \rightarrow A_{\ell-1} \rightarrow A'_{\ell\alpha} \rightarrow B_{\ell+1} \leftarrow \leftarrow \leftarrow B_{\ell\beta} \\ \hline \alpha \quad \beta \end{array} \quad (13)$

form an orthonormal basis for the orthogonal tangent space $\mathbb{T}_{|\Phi[M]\rangle}^\perp$, since

$$\langle \Phi_{\ell', \alpha'\beta'} | \Phi_{\ell, \alpha\beta} \rangle = \begin{array}{c} A \rightarrow \rightarrow \rightarrow A'_{\ell\alpha} \leftarrow \leftarrow \leftarrow B \\ \hline \alpha \quad \beta \end{array} = \delta_{\ell\ell'} \delta_{\alpha\alpha'} \delta_{\beta\beta'}$$

$$\langle \Phi_{\ell', \alpha' \beta'} | \Phi_{\ell, \alpha \beta} \rangle_M = \text{Diagram} = \delta_{\ell \ell'} \begin{bmatrix} \alpha & \beta \\ \alpha' & \beta' \end{bmatrix} = \delta_{\ell \ell'} \mathbb{1}_{\alpha'}^{\alpha} \mathbb{1}_{\beta'}^{\beta} \quad (1e)$$

[(9) ensures that terms with $\ell' \neq \ell$ vanish, and for the $\ell' = \ell$ terms, we can close zipper from left and right.]

Tangent space projector

Tangent space basis yields desired projector onto orthogonal tangent space $\Pi_{|\psi(M)\rangle}^{\perp}$:

$$\hat{P}_{\Pi_{|\psi(M)\rangle}^{\perp}} = \sum_{\ell, \alpha \beta} |\Phi_{\ell, \alpha \beta}\rangle \langle \Phi_{\ell, \alpha \beta}| = \sum_{\ell=1}^N \text{Diagram} \quad (15)$$

It is convenient to 'eliminate' the dependence on A' using

$$A'^{\sigma'} A'^{\dagger}_{\sigma} = \mathbb{1}_{\sigma}^{\alpha} \mathbb{1}_{\sigma'}^{\beta} - A^{\sigma} A^{\dagger}_{\sigma'} \quad , \quad \text{Diagram} \quad (16)$$

[Check: $\underbrace{A'^{\dagger}_{\sigma'}}_1 (A'^{\sigma'} A'^{\dagger}_{\sigma}) \stackrel{(9)}{=} A'^{\dagger}_{\sigma}$, $A^{\sigma} (A'^{\sigma'} A'^{\dagger}_{\sigma'}) \stackrel{(9)}{=} 0$]

Then

$$\hat{P}_{\Pi_{|\psi(M)\rangle}^{\perp}} = \sum_{\ell=1}^N \left[\text{Diagram} - \text{Diagram} - \text{Diagram} \right] = \sum_{\ell=1}^N \text{Diagram} \quad (17)$$

This is our final expression for desired tangent space projector. It is built fully from known tensors!

4. Time evolution

KS.4

Schrödinger equation now takes the form

$$-i \frac{d}{dt} |\psi_M(t)\rangle = \hat{P} \Pi_{|\psi_M(t)\rangle} \hat{H} |\psi_M(t)\rangle$$

$$-i \sum_{\ell} \begin{array}{c} A \quad A \quad \dot{C}_{[\ell]} \quad B \quad B \\ | \quad | \quad | \quad | \quad | \end{array} = \sum_{\ell} \begin{array}{c} A \quad A \quad C_{[\ell]} \quad B \quad B \\ | \quad | \quad | \quad | \quad | \end{array} - \begin{array}{c} A \quad A \quad A \quad \Lambda_{[\ell]} \quad B \quad B \\ | \quad | \quad | \quad | \quad | \end{array}$$

or $-i \sum_{\ell} \begin{array}{c} A \quad A \quad A \quad \dot{\Lambda}_{[\ell]} \quad B \quad B \\ | \quad | \quad | \quad | \quad | \end{array}$

$$\dot{C} = \frac{d}{dt} C = \sum_{\ell} \begin{array}{c} C_{[\ell]} \\ | \quad | \\ A \quad A \quad B \quad B \end{array} - \sum_{\ell} \begin{array}{c} \Lambda_{[\ell]} \\ | \quad | \\ A \quad A \quad B \quad B \end{array}$$

Can be integrated one site at a time:

$$C_{[\ell]}(t+\tau) = C_{[\ell]}(t) \quad \text{forward in time}$$

$$\Lambda_{[\ell]}(t+\tau) = \Lambda_{[\ell]}(t) \quad \text{backward in time}$$

Forward sweep, starting from

$$C_{[1]}(t) B_{[2]}(t) \dots B_{[N]}(t)$$

$$C_{[\ell]}(t) B_{[\ell+1]}(t) \xrightarrow{H_{[\ell]}} C_{[\ell]}(t+\tau) B_{[\ell+1]}(t)$$

$$= \underbrace{\hspace{10em}}_{B_{[\ell+1]}(t)}$$

$$\xrightarrow{K_{[\ell]}} A_{[\ell]}(t+\tau) \underbrace{\hspace{10em}}$$

$$A_{[\ell]}(t+\tau) \quad \text{etc.}$$

until we reach last site, and MPS described by

$$A_{[1]}(t+\tau) \dots A_{[N-1]}(t+\tau) C_{[N]}(t) \quad (13)$$

2. Turn around:

$$C_{[N]}(t) \xrightarrow{H_{[N]}} C_{[N]}(t+\tau) \xrightarrow{H_{[N]}} C_{[N]}(t+2\tau) \quad (14)$$

3. Backward sweep, for $\ell = N-1, \dots, 1$, starting from

$$A_{[1]}(t+\tau) \dots A_{[N-1]}(t+\tau) C_{[N]}(t+2\tau)$$

3. Backward sweep, for $l = N-1, \dots, 1$, starting from $A_{[1]}(t+\tau) \dots A_{[l-1]}(t+\tau) C_{[l]}(t+2\tau)$

$$A_{[l]}(t+\tau) C_{[l+1]}(t+2\tau) \stackrel{3(a)}{=} A_{[l]}(t+\tau) \tilde{\Lambda}_{[l]}(t+2\tau) B_{[l+1]}(t+2\tau) \quad (15)$$

$$\stackrel{K[l]}{3(b)} \rightarrow A_{[l]}(t+\tau) \underbrace{\tilde{\Lambda}_{[l]}(t+2\tau)}_{3(c)} B_{[l+1]}(t+2\tau) \quad (16)$$

$$= C_{[l]}(t+\tau) B_{[l]}(t+2\tau) \quad (17)$$

$$\stackrel{H[l]}{3(d)} \rightarrow C_{[l]}(t+2\tau) B_{[l]}(t+2\tau) \quad (18)$$

until we reach first site, and MPS described by $C_{[1]}(t+2\tau) B_{[2]}(t+2\tau) \dots B_{[N]}(t+2\tau)$

The scheme described above involves 'one-site updates'. This has the drawback (as in one-site DMRG), that it is not possible to dynamically exploring different symmetry sectors. To overcome this drawback, a 'two-site update' version of tangent space methods can be set up [Haegemann2016, App. C].

A systematic comparison of various MPS-based time evolution schemes has been performed in [Paeckel2019]. Conclusion: 2-site-update tangent space scheme is most accurate!
