

Goal: construct a network that can recognize handwritten numbers $\in \{0, 1, \dots, 9\}$ from MNIST (Modified National Institute of Standards and Technology) data set.

- contains 60000 training images, labeled by 'image ID' $n = 1, \dots, N$ and 10000 testing images

- 28x28 pixels, labeled by 'pixel ID' $l = 1, \dots, 784 := L$

- each pixel contains grey-scale value $x_n^l \in (0, 1) := I \subset \mathbb{R}$
 white black unit interval

- image n is represented by 'image vector' $\vec{x}_n = (x_n^1, \dots, x_n^L) \in I^L$

- each image has been assigned a 'target name' $\vec{t}_n \in \{\vec{e}_0, \dots, \vec{e}_9\}$,

where $\vec{e}_j = (0, 0, \dots, 1, \dots, 0)$, a basis vector in N^{10} , represents the number $j \in \{0, \dots, 9\}$

Goal: find 'decision function' \vec{f} that maps image vector to 'predicted name',

$$\vec{f}: I^L \rightarrow N^{10}, \quad \vec{x}_n \mapsto \vec{f}(\vec{x}_n) := \vec{f}_n$$

'predicted name'

while minimizing the cost function

$$C = \sum_{n=1}^N (\vec{f}_n - \vec{t}_n)^2$$

target name

[Alternatively, choose $\vec{f} \in I^{10}$, $|\vec{f}| = 1$ then f^j = probability that image is the number j]

1. Neural network

'output layer': $\vec{f} = (f^0, \dots, f^9) \in N^{10}$

'hidden layer': $\vec{y} = (y^1, \dots, y^M) \in I^M$

'input layer': $\vec{x} = (x^1, \dots, x^L) \in I^L$

Non-linear transformation:

$$y^k = \sigma \left(\underbrace{b^k}_{\text{'bias'}} + \sum_l \underbrace{w_{l,k}^k}_{\text{'weight'}} \underbrace{x^l}_{\text{'input'}} \right)$$

with $\sigma(x) = \frac{1}{1 + e^{-x}}$

'sigmoid function'

mimics neuron: 'fires' when input is above threshold

'soft-max layer':
$$f^j = \frac{e^{(a^j + u^j_l y^l)}}{\sum_{i=0}^9 e^{(a^i + u^i_l y^l)}}$$

use of exponentials emphasizes largest output at expense of others

$\vec{v} = (b, w, a, u)$ are variational parameters, used to minimize C (e.g. by gradient descent)
 \Rightarrow 'train the network' = 'supervised learning'

Multilayer networks (many layers = 'deep learning')

All of the above is just one possible Ansatz.
 Many others can and have been tried.

E.g.: multilayer networks:

hope is: will capture hierarchical structure better

As before, sigmoid functions can be used to map input to output from one layer to the next.

Optimize cost function using gradient descent: $C = C(\vec{v})$
 parameters of network (a, u, b, w)

Gradient: $-\vec{\nabla} C = -\left(\frac{\partial C}{\partial v^1}, \frac{\partial C}{\partial v^2}, \dots\right)$ points in direction of steepest descent:

New variables: $\vec{v}' = \vec{v} - \eta \vec{\nabla} C$
 'learning rate' (should be neither too small, nor too large)

2. Supervised learning with tensor networks

ML.2

[Novikov2016], [Stoudenmire2017] with Schwab; [Maier2017] Bachelor thesis of David Maier

Goal: construct decision function \vec{f} using a tensor network (here MPS);
train network using optimization techniques familiar from DMRG

Ansatz: $\vec{f} : \mathbb{I}^L \mapsto \mathbb{I}^o$, (1)

$\vec{x} \mapsto \vec{f}(\vec{x}) := \langle \vec{W} | \Phi(\vec{x}) \rangle$ (2)

image vector predicted name

where right-hand side involves two separate maps:

'feature map' $\Phi : \vec{x} \mapsto |\Phi(\vec{x})\rangle$: encodes greyscale input data into L -leg MPS, $|\Phi(\vec{x})\rangle$ (3)

'weight vector' $\vec{W} : |\Phi(\vec{x})\rangle \mapsto f^j(\vec{x}) := \langle W^j | \Phi(\vec{x}) \rangle$, $j=0, \dots, 9$ (4)

converts feature map into predicted name via inner product with an L -leg MPS, $|W^j\rangle$

'predicted name': that label j for which f^j is maximal.

Feature map: encoding input data

map color range
(0,1) = (white, black)
to quarter-unit-circle,

so that $\langle \phi(x') | \phi(x) \rangle = \sum_{\sigma=\pm} \phi_{\sigma}(x') \phi_{\sigma}(x) = \begin{cases} 1 & \text{if } x \approx x' \\ 0 & \text{if } x \approx \text{white}, x' \approx \text{black} \end{cases}$ (6)

Choose 'snake-ordering' of pixels,
and encode image in a product state MPS: ($d=2$)

$|\Phi(\vec{x})\rangle = |\phi(x^1)\rangle \otimes |\phi(x^2)\rangle \otimes \dots \otimes |\phi(x^L)\rangle$ (7)

$= \begin{matrix} \sigma_1 & \sigma_2 & \dots & \sigma_L & \dots & \sigma_L \\ \circ & \circ & \dots & \circ & \dots & \circ \\ x^1 & x^2 & \dots & x^L & \dots & x^L \end{matrix}$ (8)

This construction for $|\Phi(\vec{x})\rangle$ is not unique. Other constructions are possible, provided that

$\langle \Phi(\vec{x}') | \Phi(\vec{x}) \rangle$ is a smooth and slowly varying function of \vec{x} and \vec{x}'

which induces a 'distance matrix' in feature space which tends to cluster similar images together.

Weight vector: encoding pattern recognition

$$|W^j\rangle = \text{L-leg MPS} = \begin{array}{c} \text{---} \sigma_1 \text{---} \sigma_2 \text{---} \dots \text{---} \sigma_{l-1} \text{---} \sigma_l \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array}$$

$$= |1\rangle A^{\sigma_1} A^{\sigma_2} \dots M^{\sigma_{l-1}, j} B^{\sigma_{l-1}} B^{\sigma_l}$$

Left-normalized A's, right-normalized B's, sandwiching a 4-leg tensor, $M^{\alpha\sigma_l\beta,j}$, at site l

Decision function: $\vec{f}(x)$, with components:

$$f^j(x) \stackrel{(4)}{=} \langle W^j | \Phi(x) \rangle = \begin{array}{c} \text{---} \sigma_1 \text{---} \sigma_2 \text{---} \sigma_{l-1} \text{---} \sigma_l \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array} \stackrel{\text{global description}}{=} \begin{array}{c} \text{---} \alpha \text{---} \sigma_l \text{---} \sigma_{l+1} \text{---} \beta \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array} \stackrel{B}{=} \begin{array}{c} \text{---} \alpha \text{---} \sigma_l \text{---} \sigma_{l+1} \text{---} \beta \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array} \stackrel{f}{=} \begin{array}{c} \text{---} \alpha \text{---} \sigma_l \text{---} \sigma_{l+1} \text{---} \beta \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array}$$

$$:= \langle B^j | \tilde{\Phi}(x) \rangle, \text{ with } \langle B^j | = \begin{array}{c} \text{---} \alpha \text{---} \sigma_l \text{---} \sigma_{l+1} \text{---} \beta \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array}, \quad | \tilde{\Phi}(x) \rangle = \begin{array}{c} \text{---} \alpha \text{---} \sigma_l \text{---} \sigma_{l+1} \text{---} \beta \text{---} \\ \uparrow \quad \uparrow \quad \quad \quad \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \quad \quad \quad \sigma_l \quad \sigma_l \end{array}$$

independent of \vec{x} independent of j

Note: all x -dependence resides in $| \tilde{\Phi}(x) \rangle$, all j -dependence in $| B^j \rangle$.

Location of 'central site' can be shifted (e.g. during sweeping).

Cost function

$$C = \sum_{n=1}^N \underbrace{(\vec{f}_n - \vec{t}_n)^2}_{\sum_j (f_n^j - t_n^j)^2} = \sum_{n=1}^N \left(\begin{array}{c} \text{---} f-t \text{---} \\ \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \end{array} \right)_n, \quad \vec{f}_n := \vec{f}(\vec{x}_n)$$

evaluated at \vec{x}_n

For given set of training data $\{ \vec{x}_n, \vec{t}_n | n=1, \dots, N \}$, minimize C w.r.t. $\langle W |$, or equivalently, $\langle B |$.

Minimize using gradient steepest descent. Compute the gradient:

$$|\nabla B^j\rangle := \frac{\partial C}{\partial B^j} = z \sum_{n=1}^N (f_n^j - t_n^j) \frac{\partial f_n^j}{\partial B^j} = z \sum_{n=1}^N (f_n^j - t_n^j) | \tilde{\Phi}(\vec{x}_n) \rangle$$

sum over training set
 differs from one image to the next

$$= z \sum_{n=1}^N \left(\begin{array}{c} \text{---} f-t \text{---} \\ \uparrow \quad \uparrow \\ \sigma_l \quad \sigma_l \end{array} \right)_n$$

Then update the MPS:

$$n=1 \left(\begin{array}{c} \vee \\ \dots \\ j_n \end{array} \right)$$

Then update the MPS:

$$|B^j\rangle = |B^j\rangle - \eta (\nabla B^j) = \left[\text{MPS } B^j \right] - \eta \sum_{n=1}^N \left(\text{diamond } f-t \text{ with } \text{green, blue, purple squares} \right)_n$$

learning rate η (must be chosen very carefully!)

Advance to next site:

$$= \left[\text{MPS } B' \text{ with SVD } \sigma_l, \sigma_{l-1}, \sigma_{l+1} \right] = \left[\text{MPS } \alpha \xrightarrow{A^{\sigma_l}} \sigma_l \xrightarrow{M^j} \sigma_{l+1} \xrightarrow{\beta} \right]$$

Update training input:

Sweep back and forth until A-tensors no longer change -- then 'training of network' is complete.

Comments

Costs: $O(d^3 D^3 N \cdot L \cdot 10)$

d : physical bond dimension (here: 2) N : number of training images

D : MPS bond dimension (free parameter) L : number of pixels per image

Once network has been trained, prediction of a new image x proceeds simply via

$$f^j(x) = \langle w^j | \Phi(x) \rangle, \text{ predicted name is the } j \text{ yielding maximal } f^j$$

MNIST test:

- 28 x 28 was coarse-grained to 14 x 14 (to save resources)
- at most 5 sweeps were needed before training converges
- bond dimension $D = 10 \Rightarrow$ 5% error rate
- $20 \Rightarrow$ 2% error rate
- $120 \Rightarrow$ 0.97% error rate

Implicit feature selection - where does learning happen?

- $|\hat{\Phi}\rangle$ is projection of $|\Phi\rangle$ onto space spanned by orthonormal basis, encoded in $\langle\tilde{\mathcal{B}}|$
 has just D^2 components lives in space of dimension 2^L lives in space of dimension D^2

- So, training an MPS model uncovers relatively small set of features, and simultaneously trains decision function using only those features.
- 'Feature selection' occurs when computing SVD: basis elements which do not contribute optimally to bond tensors are discarded

Future prospects

- try tensor networks that are designed for 2D (PEPS, TRG, MERA,)
- try other sampling schemes
- incorporate symmetries (if data set is 'invariant' under translations, rotations)
- 'unsupervised learning' with tensor networks
- ...
